with MMF (1–2 g/day) and reducing corticosteroid dose. We report 24 week data.

Results In this study, 7/10 (70%) subjects achieved CR at 24 weeks. Of the 10 subjects that achieved ≥25% reduction in UPCR at 8 weeks, 80% were responders (61% reduction in UPCR over baseline) at 24 weeks. In addition, inflammatory markers such as C3, C4 and anti-dsDNA all continued to normalise to 24 weeks. Renal function remained stable. VCS was well-tolerated with no unexpected safety signals observed.

Conclusions The results suggest that early response to therapy of VCS in combination with MMF may predict 24 week CR in the presence of low steroids in active LN. 48 week CR data will be presented at the meeting.

Parallel Session 7: Manifestations, comorbidities and complications

21 INFECTIONS IN THE ASIA PACIFIC REGION
W Louthrenoo*. Faculty of Medicine- Chiang Mai University, Division of Rheumatology- Department of Internal Medicine, Chiang Mai, Thailand
10.1136/lupus-2017-000215.21

Infections in the Asia Pacific Region Infections in patients with systemic lupus erythematosus (SLE) are not uncommon, and are major causes of morbidity and mortality. The prevalence of infections is high among developing countries, and those with low socioeconomic status, particularly in Asia. Dysregulation of the immune system by the disease itself and the use of corticosteroids and immunosuppressive drugs increase susceptibility to infection, which can cause by both usual and opportunistic pathogens. Infections caused by viruses, bacteria, mycobacterium, fungi, and parasites have been described. Varicella zoster, Salmonella spp., both Mycobacterium tuberculosis and non-tuberculosis, Nocardia spp., Aspergillus spp., Pneumocystis jiroveci, etc. are common opportunistic pathogens.

Diagnosing infections in SLE is sometimes difficult. Acute infections can cause protein manifestations that sometimes simulate disease flare. Atypical presentations are not uncommon. Fever and leukocytosis might not be present due to the use of corticosteroids and immunosuppressive drugs. Occult infections can be overlooked if not searched for carefully. Furthermore, infections themselves can trigger disease flare. A high level of hsCRP correlates well with infection. Procalcitonin can be used as a marker for bacterial infection.

Treatment of infections in SLE also is problematic. Use of high dose corticosteroids and immunosuppressive drugs to control SLE activity can reactivate latent infections, or exacerbate current infections, making them more difficult to control. Infections should be suspicious in SLE patients with fever or clinical presentations that do not respond to appropriate SLE treatment. Appropriate evaluation is needed and treatment should be started immediately to cover pathogens most likely possible, and prevent morbidity and mortality.

Parallel Session 8: Innate immunity and interferon

22 MYOCARDIAL DIFFUSION WEIGHTED IMAGING REVEALS SUBCLINICAL MYOCARDIAL INFLAMMATION IN PATIENTS WITH SYSTEMIC LUPUS ERYTHEMATOSUS
Q Yan†, Q Wu, Q Guo. Renji Hospital- School of Medicine- Shanghai Jiao Tong University, Department of Rheumatology, Shanghai, China; 2Renji Hospital- School of Medicine- Shanghai Jiao Tong University, Department of Radiology, Shanghai, China

Background and Aims To evaluate whether diffusion weighted imaging can assess myocardial oedema in patients with systemic lupus erythematosus (SLE).

Methods 32 patients (mean age 36±8 years) with SLE and 20 controls (mean age 47±6 years) underwent cardiac MRI at 3.0 T. Standard cine images were obtained. DWI and T2 mapping were acquired in a mid-cavity short-axis plane. Late gadolinium enhancement (LGE) images were obtained 15 min after 0.2 mmol/kg of contrast. All patient were subdivided into to late gadolinium enhancement-positive (LGE+) and LGE-negative (LGE-) group according to the presence and absence of enhancement on LGE image.

Results SLE patients had low disease activity (mean SLE disease activity index score 0.74±0.5). There were no differences in LV size or function between SLE patients and controls. Only 11 subjects had LGE. SLE LGE+ subjects had highest ADC value among the three groups. SLE LGE+ subjects had higher ADC (apparent diffusion coefficient) than LGE- subjects. SLE LGE- subjects had higher ADC than control (p<0.05). T2 value of SLE LGE+ was no significant difference with SLE LGE- subjects. Repeated measures were highly correlated by linear regression for both inter- and intraobserver analysis (both R=0.75, p<0.001). ADC mapping identifies increased in SLE patients, likely due to subclinical myocardial oedema.

Conclusions These findings suggest that even in SLE patients with inactive disease and normal cardiac function, ADC mapping as a novel quantitative and highly reproducible technique can detect low grade myocardial inflammation.

23 CYCLIN DEPENDENT KINASE 1: A NOVEL REGULATOR CONTROLLING TYPE I INTERFERON SIGNALING AND POTENTIAL TARGET FOR THERAPEUTIC INTERVENTION IN SLE
Y Qin, N Shen. Renji Hospital- School of Medicine- Shanghai Jiao Tong University, Shanghai Institute of Rheumatology, Shanghai, China; 2Medical Centre, The Centre for Autoimmune Genomics and Aetiology CAGE, Cincinnati- Ohio, USA
10.1136/lupus-2017-000215.23

Background and Aims Abnormal epigenetic changes are involved in over-activated pathogenic IFN signalling in SLE. However, the mechanisms are still not clear. We tried to identify novel epigenetic regulators of IFN signalling pathways in SLE.

Infections in patients with systemic lupus erythematosus (SLE) are not uncommon, and are major causes of morbidity and mortality. The prevalence of infections is high among developing countries, and those with low socioeconomic status, particularly in Asia. Dysregulation of the immune system by the disease itself and the use of corticosteroids and immunosuppressive drugs increase susceptibility to infection, which can cause by both usual and opportunistic pathogens. Infections caused by viruses, bacteria, mycobacterium, fungi, and parasites have been described. Diagnosing infections in SLE is sometimes difficult. Acute infections can cause protein manifestations that sometimes simulate disease flare. Atypical presentations are not uncommon. Fever and leukocytosis might not be present due to the use of corticosteroids and immunosuppressive drugs. Occult infections can be overlooked if not searched for carefully. Furthermore, infections themselves can trigger disease flare. A high level of hsCRP correlates well with infection. Procalcitonin can be used as a marker for bacterial infection.

Treatment of infections in SLE also is problematic. Use of high dose corticosteroids and immunosuppressive drugs to control SLE activity can reactivate latent infections, or exacerbate current infections, making them more difficult to control. Infections should be suspicious in SLE patients with fever or clinical presentations that do not respond to appropriate SLE treatment. Appropriate evaluation is needed and treatment should be started immediately to cover pathogens most likely possible, and prevent morbidity and mortality.
Methods We screened 463 epigenetic regulatory genes using a siRNA library in a high-throughput ISRE-luciferase assay. Q-PCR and Western blot were used to study the function of targeted genes.

Results Among those genes which significantly enhanced or inhibited ISRE activity, CDK1 had a differential expression in PBMCs and renal biopsies between SLE patients and healthy controls and was positively correlated with "IFN scores" and disease activities of SLE patients. We revealed that the expression of ISGs and phosphorylation of STAT1 could be reduced by knocking down CDK1, while over-expression of CDK1 produced an opposite effect. As specific inhibitors of IFN pathway has emerged as a promising treatment for SLE and CDK1 inhibitors are being on trial for some types of cancer, we wondered whether CDK1 inhibitor could be a potential repositioning drug for SLE. We found a CDK1 inhibitor, RO-3306, could alleviate FN in PBMCs from 5 SLE patients who had high IFN scores. We found that RO-3306 significantly reduced ISGs expression in these cells. Our preliminary data further showed that RO-3306 could reduce proteinuria in SLE mouse model.

Conclusions We proposed that CDK1 is a novel positive regulator of IFN signalling pathway, over-expression of CDK1 in SLE might contribute to the over-activated IFN signalling and inhibition of CDK1 could be used to interfere abnormal IFN signalling in SLE.

A MOLECULAR SIGNATURE BASED ON IFN GENE SIGNATURE AND SEROLOGY DEFINES TWO POPULATIONS OF PATIENTS WITH DIFFERENT BASELINE DISEASE ACTIVITY

Background and Aims Randomised controlled trials in SLE have shown that response to treatment is influenced by baseline disease activity. The current investigation used objective molecular and biochemical baseline parameters to characterise SLE patients in two large multinational trials (n=2262 patients).

Methods Patients were categorised with four dichotomous baseline parameters. SLE(+) was defined by any of the following: IFN signature (high), anti-dsDNA (+), C3 (low) and/or C4 (low). SLE(-) required all of the following: IFN signature (normal), anti-dsDNA (-), C3 (normal) and C4 (normal).

Results Baseline RNA transcript data were available for 1747 of 2262 patients. When IFN status was combined with the serology criteria, 1500 (86%) were classified as SLE(+) and 247 (14%) were classified as SLE(-). At baseline, SLE(+) patients had significantly lower mean SLEDAI scores (8.3) compared to SLE(+) (10.7). Baseline SLEDAI <10 was observed in 72% of SLE(-) compared to 38% of SLE(+). The proportion on corticosteroids at baseline was 49% in SLE(-) compared to 78% in SLE(+); the proportion on immunosuppressants at baseline was 31% in SLE(-) compared to 44% in SLE(+). In the US, 22% were SLE(-) compared to 10% for Latin America, 7% for Europe, and 5% for ROW.

Conclusions A subset of clinical trial patients was identified using biochemical and molecular markers with high sensitivity for SLE. Seronegative SLE patients with normal IFN gene signature had lower disease activity and were taking less background medication at baseline, two factors which have been negatively associated with response to treatment in some previous trials.
