Background and aims The association among SLEDAI, SF-36, and HADS-D was significantly correlated with SF-36 and HADS-A independently. The regression equation was SLEDAI = 0.461 + 1.114*HADS-A (p=0.011) and “SLEDAI=0.461+1.114*HADS-A” (p=0.028).

Conclusions SSDM is an effective mobile interface to serve for SLE patients performing self-management as well as to supply physicians with valuable data. SLEDAI was significantly correlated with SF-36 and HADS-A independently.

Methods SSDM includes physicians’ and patients’ application system. The patient application system includes SSDM, SF-36, HADS, and medication management. After data entry, patients can synchronise data to the mobile terminal of authorised rheumatologist. All patients fulfilling the 1997 ACR criteria for SLE were recruited.

Results A total of 3717 SLE patients from 490 rheumatologists in 214 rheumatology centres across China participated in the study (89% were women). The mean age was 34.09±11.87 years and the median disease duration was 3.15 years. 1,908 patients performed self-assessment for 3085 times. The mean score of SLEDAI, SF-36, HADS-Anxiety (HADS-A) and HADS-Depression (HADS-D) were 9.41±2.52, 60.09±20.01, 7.86±4.09 and 8.77±4.25 respectively. According to the SLEDAI criteria, 43.71%, 18.50%, 13.42% and 24.37% patients achieved Remission, Low, Moderate and High disease activity. SLEDAI was significantly correlated with SF-36 and HADS-A independently. The regression equation was “SLEDAI=21.753–0.179*SF-36” (p=0.011) and “SLEDAI=0.461+1.114*HADS-A” (p=0.028).

Conclusions SSDM is an effective mobile interface to serve for SLE patients performing self-management as well as to supply physicians with valuable data. SSDM is an effective mobile interface to serve for SLE patients performing self-management as well as to supply physicians with valuable data.

Background and aims Hydroxychloroquine (HCQ) is used by the majority of patients who have incomplete lupus erythematosus (ILE), defined as positive ANA and 1–2 other criteria for SLE, although efficacy in this situation has never been proven in a rigorous clinical trial. The Study of anti-Malarials in Incomplete Lupus Erythematosus (SMILE) is a proposed placebo-controlled trial of HCQ in ILE designed to measure the effect of drug on progression to SLE. In order to judge trial feasibility, “mock recruitment” was performed.

Methods 45 patients seen in outpatient clinics of the SMILE investigators for ANA and musculoskeletal or cutaneous complaints were interviewed using a structured script explaining the need for the trial, potential risks and benefits of HCQ and the possible randomization to placebo. They were then asked questions to ascertain their understanding of the trial and their willingness to enrol.

Results 96% of the subjects were female; median age was 35 and median symptom duration 3 years. 13% were Hispanic and 13% were African American. 18% had a personal history of autoimmune disease other than lupus; 42% had a family history. Musculoskeletal and cutaneous symptoms were each in 60% of subjects. 73% of subjects were interested, and 64% were likely to enrol. The most common reason for disinterest was lack of time to participate (50%), risks of HCQ (25%) and possibility of getting placebo (19%).

Conclusions A placebo-controlled clinical trial is feasible when the standard of care is an approved drug. 50% more subjects need to be screened to have enough to enrol in the trial.

Background and aims Psoriasis is a TH1 and TH17 cells-dependent autoimmune disease of the skin and joint while allergic disorders are TH2 cell-dependent. There are conflicting reports about the effect of atopy on psoriasis. With regard to these reports, the aim of the current study was to determine the frequency of atopy, allergic disorder (such as allergic rhinitis, asthma and eczema) and eosinophilia in patients with psoriasis.

Methods For this purpose, this case-control study was performed in Maszhad Ghaem hospital. History of allergic diseases including: allergic rhinitis, asthma and eczema were evaluated based on ISAAC standard questionnaire. Skin prick test was performed with 5 common allergen in our region and atopy was defined as a result of only one positive skin prick test.
Background and aims To investigate the prevalence of sleep disorders and the relevant determinants in a cohort of SLE patients.

Methods One hundred patients with SLE were included in the study. Sleep quality was assessed using the Pittsburgh Sleep Quality Index (PSQI). Depression, anxiety, quality of life, and fatigue were evaluated by PHQ-9, GAD-7, SF-36, and VAS respectively. The demographic and clinical data were also recorded. SLE disease activity and damage severity were assessed by SLEDAI and SDI respectively.

Results The prevalence of sleep disorders in SLE patients was 42%. Compared with patients without sleep disorders, the ratio of males and married patients, age, the score of SLEDAI, PHQ-9, GAD-7, and fatigue were higher in SLE patients with sleep disorders, while the score of SF-36 was lower (p<0.05). Age, SLEDAI, PHQ-9, GAD-7, and fatigue correlated positively with sleep disorders (p<0.05). C3 and the score of SF-36 correlated negatively with sleep disorders (p<0.05). In multiple logistic regression analyses, gender, anxiety, body pain, and energy were the independent determinants of sleep disorders (R²=0.494, P<0.01).

Conclusions Poor sleep quality is common in SLE patients. Gender, age, disease activity and severity, anxiety, depressed mood, and quality of life contribute significantly to sleep disorders in SLE.

Background and aims One phase III study has reported that Leflunomide (LEF) in combination with prednisone was effective in the induction therapy of proliferative lupus nephritis (LN). However, long-term data of LEF in the maintenance treatment of LN are lacking. The aim of this study was to investigate the long-term outcomes of LEF in the maintenance treatment of LN in an open-label extension of a prospective multi-centre observational study.

Methods 70 patients were enrolled into LEF induction group with a loading dose of 50 mg/day for 3 days, followed by 30 mg/day for six months. The partial and complete remission rate was 52% and 21%. Among them, 15 patients voluntarily entered an open labelled extension study. Data for survival and kidney function were prospectively collected during a 12 year period for the 15 patients who were maintained on 20 mg/day LEF.

Results 15 patients (mean age 40.2±7.4 years; 86.6% female) were treated with LEF for >12 months, the mean duration of LEF treatment was 11.8 years. During a median follow-up period of 12.3 years, 1 patient died from sepsis, 4 patients developed renal flare. The 12 year cumulative survival rates for the composite end point of death and chronic renal failure were 93.3% and 100%, respectively. At the final follow-up, the complete remission rate in the remaining patients was 71.43%, the partial remission rate was 28.57%, the mean proteinuria level was 0.33g/day (range 0.07–1.62 g/day), and the mean serum creatinine level was 62.3 μmol/L.

Conclusions Our data suggest that a remission-inducing regimen of LEF followed by maintenance therapy with LEF resulted in good long-term patient survival and renal preservation.
