disease process and are likely to pave the way towards identifying disease biomarkers for early-diagnosis of LN.

**Background and aims** The anti-CD20 agent rituximab (RTX) is generally reserved for the treatment of refractory SLE. Whist response is variable no clear predictors of early response have been confirmed. We aimed to explore factors that predict early response to RTX in a nationwide cohort of patients receiving their first RTX course.

**Methods** The BILAG-BR has recruited patients with refractory SLE starting RTX in the UK since Sept 2010. For this analysis we included patients who received RTX up to November 2015, had active disease at baseline, and had disease activity indices reported at baseline and 6 months. Response was defined as improvement of all active BILAG 2004 systems with no worsening in other systems or SLEDAI-2K; and no increase in glucocorticoid dose at 6 months.

**Results** In 197 patients (90.36% females) 99 (50.8%) responded at 6 months. In a multivariable model with imputation for missing variables, concomitant IV cyclophosphamide was associated with better response. A higher baseline global BILAG-2004 score was associated with lower rates of response (Table 1).

**Conclusions** Early response to RTX in refractory SLE was associated with use of concomitant cyclophosphamide, higher glucocorticoid doses and lower baseline disease activity. Serology and demographic factors did not predict response. Understanding how concomitant therapy improves longer-term responses and identifying novel biomarkers of response will improve patient selection and overall outcomes for patients receiving this therapy.

**Results** Serum IL-3 levels correlated with serum IFNα (r=0.612, 95% CI 0.455–0.733, p<0.001). IL-3 stimulation in vitro altered 794 genes (−1≥logFC ≥1, FDR<0.05). Thirty-five of these genes overlapped with differentially expressed genes between SLE and HD. These 35 genes were expressed in 28/31 SLE donors, revealing the presence of an ‘IL-3 gene signature’. There was strong correlation between the IL-3 signature and an IFN signature determined by hierarchical clustering of the five hundred most variable genes in SLE donors (r=0.939, 95% CI 0.898–0.964, p<0.0001).

**Conclusions** We have previously reported a novel anti-IL-3Rα mAb (CSL362/JNJ-473), which depletes pDCs and reduces IFNα production, as well as neutralising IL-3 signalling (Oon S, JCI Insight, 2016). An association between IL-3 and IFNα was found in this study, raising the possibility that CSL362 may be especially useful for lupus patients with a dual IL-3/IFN gene signature.

**URINARY VCAM 1 AS A DISEASE ACTIVITY INDICATOR IN LUPUS NEPHRITIS**

S Padma*, J Mathew, S Vijayakumar. Christian Medical College, RHEUMATOLOGY, Vellore- Tamilnadu, India; Christian Medical College, NEPHROLOGY, Vellore- Tamilnadu, India

**Background and aims** Currently we do not have a biomarker that can closely reflect the renal disease activity. So the aim of this study is to study the utility of urinary VCAM 1 (Vascular cell adhesion molecule 1) in lupus nephritis.

**Methods** It was a diagnostic case control study. The patients presenting to Rheumatology outpatient department were recruited. Patients were divided into 2 groups, SLE without active nephritis and SLE with active nephritis based on the renal SLEDAI. Urinary VCAM1 was tested in all patients using an early morning spot urine sample using ELISA. Renal biopsy was done in patients with active nephritis. VCAM1 levels were compared with the renal SLEDAI, renal biopsy disease activity (ISN/RPS) and standard of care markers. The results were analysed using SPSS software version 16. The validity and predictive value statistics was presented with 95 percent confidence interval.

**Results** Urinary VCAM 1 levels had significant correlation (p=0.01) with disease activity based on renal SLEDAI. However, the correlation between the biopsy findings and VCAM levels was not statistically significant. Class 4 and 5 lupus nephritis had higher VCAM level than the lower classes. A positive correlation (r=0.38) was found between VCAM 1 and double stranded DNA. There was a negative correlation between C3 value and VCAM (r=−0.19). The sensitivity and specificity of urinary VCAM 1 is 65.22% and 75% respectively. The cut off value of VCAM is 23.8 pg/mg of creatinine.

**Conclusions** Urinary VCAM 1 may not independently, but combined with other markers may be a promising biomarker for disease activity in lupus nephritis.
