uptake pattern was significantly lower in HAVS than in primary RP.

Conclusions There were significant differences in hand perfusion scintigraphic features between primary RP and HAVS. These results suggest that the underlying pathophysiology of the two diseases differs; thus, different criteria should be applied for their evaluation.

**372** CLINICAL FEATURES, OUTCOMES AND RISK FACTORS FOR THE DEVELOPMENT OF POSTERIOR REVERSIBLE ENCEPHALOPATHY SYNDROME (PRES) IN THAI PATIENTS WITH SYSTEMIC LUPUS ERYTHEMATOSUS (SLE)

1U Damrongpipatkul, 2N Kasitanon, 3K Oranratanachai, 4W Louthreno*. 1Faculty of Medicine Chiang Mai University, Division of Rheumatology Department of Internal Medicine, Chiang Mai, Thailand; 2Faculty of Medicine Chiang Mai University, Division of Neuroimaging and Interventional Radiology Department of Radiology, Chiang Mai, Thailand

10.1136/lupus-2017-000215.372

**Background and aims** PRES in SLE is increasingly recognised. This study aimed at determining the prevalence, clinical features, brain imaging findings, risk factors, and outcomes of PRES in Thai SLE patients.

**Methods** SLE patients with PRES seen between 1 January 1986 and 31 August 2013 were identified. Controls were matched with hospital number and disease duration to cases (ratio, 1:4). Clinical features, brain imaging patterns, risk factors, treatment and outcome of PRES were determined.

**Results** Of 1141 SLE patients, 26 PRES episodes occurred 20 in females (prevalence 1.8%). Mean±SD age at diagnosis and disease duration was 29.3±13.1 and 2.8±3.4 years, respectively. Among the 26 episodes, 24 (92.3%) had seizure, 14 (53.8%) headache, 9 (34.6%) fever and vomiting and 8 (30.8%) visual disturbance. All of them had acutely elevated blood pressure. 20 and 23 patients had active lupus nephritis (LN) within 3 months prior to and at PRES onset, respectively. Dominant parietal-occipital pattern was the most common brain imaging abnormality. 22 episodes improved with blood pressure control. Immunosuppressive therapy was given for active disease in 8 episodes. Anti-convulsive therapy could be discontinued in 21 of 22 episodes (median duration 3 months). Auto-immune hemolytic anaemia (AIHA) and LN were PRES risk factors (OR 6.55, 95% CI 1.09–39.39, p=0.04 and OR 3.06, 95% CI 1.12–8.39, p=0.03, respectively). 6 patients (23.1%) died during PRES episodes. The mortality rate in SLE patients with PRES was significantly higher than those without (30% vs. 10%, p<0.001).

**Conclusions** The mortality rate was high in Thai SLE with PRES. AIHA and LN were risk factors for PRES.

**374** ANA NEGATIVE RENAL LIMITED LUPUS NEPHRITIS – A RARE ENTITY

1SP Nagaraju*, 1RP Attur, 1D Rangaswamy, 2SL Koulmame Laxminarayana, 3SP Rao, 5Kaza, 1K Saraf, 1S Shenoy, 1M Bhajarajaa, 1Rangaswamy, 1V Maheshaa, 1Kasturba Medical college- Manipal University. **Background and aims** Antinuclear antibodies (ANA) in serum is considered a decisive diagnostic test for SLE. ANA negative SLE is a subgroup of SLE that is infrequently recognised. We report an unusual case of seronegative SLE which presented...
