determined by the European consensus criteria (complete/clinical remission ± immunosuppressive drugs). The increase in SLE damage index (SDI) in the preceding 5 years was compared between patients who were and were not in remission for ≥5 years. QOL of patients as assessed by the validated Chinese version of the SF36 and the LupusPRO.

Results 769 SLE patients were studied (92% women; age 46.4 ± 14.6 years, SLE duration 12.6 ± 8.1 years). Clinical remission (serologically active) was present in 259 (33.7%) patients (median 43 months) and complete remission (clinically and serologically inactive) was present in 280 (36.4%) patients (median 51 months). Clinical and complete remission for ≥5 years was achieved in 64 (8.3%) and 129 (16.8%) of the patients, respectively. 53 (6.9%) patients in remission ≥5 years were taken off all medications including HCO. Patients remitted for ≥5 years were older, and had significantly lower prevalence of renal and haematological disease. Moreover, these patients had significantly less SDI increment than those who did not remit (0.17 ± 0.53 vs 0.67 ± 1.10; p < 0.001). Among 453 patients who had QOL assessment within 6 months of last visit, remission for ≥5 years was associated with significantly better SF36 and the health-related scores of the LupusPRO.

Conclusions Durable drug-free remission in SLE is uncommon. Patients with complete or clinical remission for ≥5 years have significantly less damage accrual and better QOL.

**SERUM 25-HYDROXYVITAMIN D3 LEVELS AND FLARES OF SYSTEMIC LUPUS ERYTHEMATOSUS: A LONGITUDINAL COHORT ANALYSIS**

1CC Mok*, 2R Singh, 3P Jannetto. 1Hong Kong S.A.R; 2Mayo Clinic, Laboratory Medicine and Pathology, Rochester, USA

Background and aims To study the relationship between serum 25-hydroxyvitamin D3 levels and flares of SLE in a longitudinal cohort of Chinese patients.

Methods Patients who fulfilled the ACR criteria for SLE were recruited and serum levels of 25-hydroxyvitamin D3 were assayed by liquid chromatography tandem mass spectrometry. Patients were stratified according to the 25-hydroxyvitamin D3 levels (group I: <15 ng/ml, deficiency; group II: 15–30 ng/ml, insufficiency; and group III: >30 ng/ml, adequate) and were serially assessed for disease activity and flares. Baseline and summated SLEDAI over time, and the annual incidence of lupus flares were compared among these groups.

Results 276 SLE patients were studied (94% women; age 41.0 ± 13.8 years; SLE duration 8.7 ± 6.6 years). 25-hydroxyvitamin D3 levels of <15, 15–30 and >30 ng/ml occurred in 26%, 54% and 20% of the patients, respectively. Group I had significantly higher baseline SLEDAI. After a follow-up of 32.5 ± 5.5 months, 153 mild/moderate and 91 severe flares developed. The mean summed SLEDAI was 3.2 ± 2.0 in group I, 2.4 ± 1.9 in group II and 2.7 ± 2.1 in group III patients (p = 0.02). The annual incidence of mild/moderate and severe flares was 0.26 ± 0.39 and 0.20 ± 0.45 (group I); 0.20 ± 0.33 and 0.09 ± 0.22 (group II); and 0.20 ± 0.32 and 0.14 ± 0.46 group III, respectively (p > 0.05). In a subgroup of 73 patients who were clinically and serologically quiescent at baseline, a similar trend of more flares was again observed in group I. New damage or vascular events did not differ significantly among the three groups.

Conclusions Vitamin D deficiency was frequent in SLE patients and was associated with more active disease at baseline and over time, as well as a trend of more severe lupus flares.

**PROLONGED REMISSION IN PATIENTS WITH LUPUS NEPHRITS**

1D Monova, 2S Monov*, 3E Peneva. 1Medical University – Sofia; Medical Institute, Department of Internal Diseases, Sofia, Bulgaria; 2Medical University – Sofia, Department of Internal Diseases; Clinic of Rheumatology, Sofia, Bulgaria; 3Medical Institute, Department of Internal Diseases, Sofia, Bulgaria

Background and aims The aim of this study is to assess the prevalence of prolonged remission in patients with lupus nephritis (LN) and its relationship with damage accrual.

Methods 318 patients diagnosed with LN between 1990 and 2015 were included in the study. We defined remission as prolonged when lasting ≥5 consecutive years. (proteinuria ≤ 0.3 g/L and serum creatinine ≤ 133.6 μmol/L) Three levels of remission were defined using the SLE Disease Activity Index-2000 (SLEDAI-2K): complete remission: no disease activity in corticosteroid-free and immunosuppressant-free patients; clinical remission off corticosteroids: serologically active clinical quiescent (SACQ) disease in corticosteroid-free patients and clinical remission on corticosteroids: SACQ disease in patients taking prednisone 5–10 mg/24 hour. Damage was measured by the SLICC/American College of Rheumatology Damage Index (SDI).

Results 318 patients (293 women) fulfilled inclusion criteria. During the 10 year follow-up, 52 patients (16.35%) achieved prolonged complete remission, 107 (33.65%) prolonged clinical remission off corticosteroids and 114 (35.85%) prolonged clinical remission on corticosteroids. SDI increased more frequently in unremitted than in remitted patients (p < 0.05); SDI median increase was higher in unremitted than in remitted patients. At multivariate analysis, unremitted disease and high-dose corticosteroid intake were risk factors for damage accrual.

Conclusions Patients with prolonged remission was associated with a better outcome in terms of damage accrual.

**INCREASED CYSTATIN C/CREATININE RATIO REFLECTS HIGH DISEASE ACTIVITY IN PATIENTS WITH SYSTEMIC LUPUS ERYTHEMATOSUS**

1S Nishiyama*, 2K Ohashi, 3T Aita, 4Y Yoshinaga, 5M Miyawaki. 1Kurashiki Medical Centre, Rheumatic Disease Centre, Kurashiki, Japan; 2Okayama University Graduate School of Medicine- Dentistry and Pharmaceutical Sciences, Department of Nephrology-Rheumatology- Endocrinology and Metabolism, Okayama, Japan

Background and aims To investigate relationship between cystatin C (Cys)/creatinine ratio and disease activity of systemic lupus erythematosus (SLE).

Methods Clinical and laboratory data were collected from 52 patients with SLE who had been examined their Cys at least once. Female rate was 96.2% and the average age±standard deviation was 47.9 ± 13.2 years old. Estimated GFR (eGFR) was calculated based on Cys (eGFRcys) and creatinine
