Baseline prednisone doses were similar between groups (Table 1). Across the population, cumulative prednisone dose over 52 weeks was significantly lower in the belimumab group versus placebo (p=0.0005; Table 1). For subjects with baseline dose >7.5 mg/day, the median number of days that prednisone dose was £7.5 mg/day and/or reduced by 50% was zero in both groups; however, the 75th percentile was larger for belimumab (213.5 days) versus placebo (172.0), reflecting the subjects who achieved longer durations of reduced steroid use within the belimumab group (p=0.0288; Figure 1). More subjects in the belimumab group had a dose reduction of ≤25% to ≤7.5 mg/day during Weeks 40–52 (belimumab, 15.6%; placebo, 10.9%; p=0.0721). Adverse event incidences were similar (belimumab, 75.7%; placebo, 74.9%).

Conclusions These results suggest belimumab is more effective than placebo in reducing steroid use across 52 weeks in this population.

Abstract 106 Figure 1

Background and aims S-Adenosyl-l-homocysteine hydrolase (SAHH) is a highly conserved ubiquitous enzyme that catalyses the hydrolysis of S-adenosyl-l-homocysteine (SAH) to adenosine (Ado) and homocysteine (Hcy) in eukaryotic cells. The reversible type III SAHH inhibitor DZ2002 has been found to have an immunomodulatory function and to alleviate disease in several inflammatory and autoimmune animal models, with greatly reduced cytotoxicity. This study was aim to examine the therapeutic effects and underlying mechanisms of DZ2002 on lupus-prone female NZB/W F1 mice.

Methods NZB/W F1 mice were treated orally with DZ2002 (0.5 mg kg⁻¹) for 11 weeks, and the proteinuria level and body weight were monitored. After the mice were euthanized, serum biochemical parameters and renal damage were determined. Splenocytes of NZB/W F1 mice were isolated for ex
Iguratimod (IGT) is a small molecular immunosuppressive drug and has been approved for treating rheumatoid arthritis. In our previous work, IGT ameliorates lupus-like disease in MRL/lpr mice by inhibiting abnormal B cell differentiation. The aim of this study is to further investigate the effects of IGT on human B cells.

Methods We established a set of stimulations to induce naive human B cell into plasmablast (PB) in vitro. We also enrolled 7 patients with refractory lupus nephritis (LN) to assess the potential efficacy of IGT.

Results IGT significantly attenuates the generation of CD19+CD20-CD27hiCD38hi plasma cells upon both BCR-dependent and independent stimulations. IGT affects neither proliferation or apoptosis of B cell in vitro. In further investigation on B cell differentiation signalling pathways, we identify that Blimp-1 and Xbp-1 can be remarkably impaired by IGT both in transcriptional and protein level; while Jak/STAT or NF-kB signalling are intact with IGT treatment. For explosive clinical study, seven patients with refractory LN were enrolled and administrated with IGT and steroids. ALL of these patients surprisingly show improved proteinuria after 8 week treatment. One patient quit the treatment because of anaemia. Four patients showed lipid profile deterioration which was adequately controlled with statin. Four patients showed lipid profile deterioration which was adequately controlled with statin. Four patients showed lipid profile deterioration which was adequately controlled with statin. Four patients showed lipid profile deterioration which was adequately controlled with statin.

Conclusions IGT has a unique effect to arrest B cell terminal differentiation, which provides strong evidence that this drug could be a new candidate drug to treat B cell related autoimmune diseases such as lupus.

Background and aims Preliminary data suggested efficacy of sirolimus in treatment of lupus nephritis (LN), but its long-term efficacy and tolerability data is lacking.

Methods We reviewed Class III/IV/V LN patients who received prednisolone and sirolimus either as initial or maintenance treatment during Jan 2007 to Jan 2016.

Results Sixteen patients were included (duration of sirolimus treatment: 27.2±19.6 months). Ten patients received sirolimus due to intolerance to standard immunosuppressive treatments and six patients because of a history of malignancy. Five patients received sirolimus during active LN, and showed improvement in proteinuria (2.8±1.9 g/day and 0.1±0.1 g/day at baseline and 36 months, p=0.011 compared to baseline), anti-dsDNA (107.7±91.9 IU/mL and 37.0±55.4 IU/mL at baseline and 36 months, p=0.145) and C3 (54.8±26.1 mg/dL and 86.3±18.6 mg/dL at baseline and 36 months, p=0.084). Eleven patients received sirolimus during disease quiescence, and showed significant improvement in C3 (90.4±18.1 mg/dL and 117.7±25.1 mg/dL at baseline and 36 months, p=0.025) and stable renal function (58.5±2.5 mL/min and 56.7±29.0 mL/min at baseline and 36 months, p=0.199) and proteinuria (0.8±0.7 g/day and 0.7±0.7 g/day at baseline and 36 months, p=0.263). One patient, whose serum creatinine was 244 μmol/L when sirolimus was started, developed renal failure after 27 months. Renal flare occurred in one patient after 36 months. Sirolimus was discontinued in five patients including one with leucopenia. Four patients showed lipid profile deterioration which was adequately controlled with statin.

Conclusions Sirolimus can be an alternative treatment option for LN and the long-term results do not suggest excessive adverse effects.
