Background and aims Antimalarials (AMs) have been shown to exert a reduced risk of damage accrual in North American and European SLE patients. We are presenting data from Latin American patients.

Methods Patients with a recent SLE diagnosis (≤2 years) from the GLADEL cohort were studied. End-point: Increase in damage (SLICC Damage Index, SDI) since cohort entry.

Results Independent (socio-demographic, clinical laboratory and treatment) variables were included. The effect of AMs use on damage (adjusting for potential confounders) was examined with a multivariable Cox regression model with a stepwise selection algorithm (variables retained in the model α: 0.05). AMs was a time-dependent variable (user: patient receiving AMs during the previous 30 days) in the regression model.

Results Of the 1466 patients included in this analysis 1049 (72%) received AMs during follow-up (as defined); median exposure time: 30 months (Q1-Q3: 11–57 months). Damage accrual occurred in 665 (45%) patients during a median follow-up time of 24 months (Q1-Q3: 8–55 months). After adjusting for potential confounders (SDI at cohort entry, socioeconomic status, disease duration at cohort entry, malar rash, photosensitivity, serositis, oral glucocorticoids, pulse glucocorticoids and SLIDEAI at cohort entry) at any time during follow-up, a patient on AMs had a 25% lower risk of damage accrual than a patient not on AMs (adjusted HR 0.75, 95% CI 0.62–0.90).

Conclusions After adjustment for possible confounding factors related to AMs use and damage accrual, AMs were independently associated with a reduced risk of damage accrual in this cohort.

193 MASSIVE PERICARDIAL EFFUSION IN YOUNG FEMALE OF SYSTEMIC LUPUS ERYTHEMATOSUS

D.M. Rangkuti. Medan, Indonesia

10.1136/lupus-2017-000215.193

Background and aims Systemic lupus erythematosus (SLE) is an autoimmune disease that has a variety of complications in all organs of the body. Pericardial effusion in the one manifestation SLE of the heart and an emergency nature. Massive pericardial effusion may result failure in cardiac pumping that is often referred to cardiac tamponade. Searching for the causes of pericardial effusion is required for diagnosis and therapy.

Methods A woman, 19 years old with complaints of chest pain and shortness of breath. Pale, joint pain, fever and weight loss.

On examination found tachycardia, pallor, muffled heart sounds, bilateral pleural effusions, and pretilial oedema.

Laboratories: Hb 8.6 g/dl, leukocytes 5900/mm³, Ht 27.7%, PLT 192,000/mm³, urea 97.9 mg/dl, creatinine 1,51 mg/dl, ferri- tin >2000 ng/ml, FE 17 mg/dl, TIBC 103 ug/dl, albumin 2.1 g/dl, 68.9 ANA test positive, Anti ds-DNA in 2754, CRP positive. Echocardiography showed massive pericardial effusion Φ 30.2 mm. Fluid analysis: reddish colour, pH 7.9, 0.178 × 103 WBC/uL, 0.005 × 106 RBC/uL, MN cells 36%, and 64% PMN cells.

Diagnosed was done SLE with massive pericardial effusion.

Therapy: pulse steroids and mfnf. Antibiotic, diuretic, ACEi, deferoxamine and antipyretic. Patients do pericardiasynthesis.

Results After all therapy for 5 days of treatment, the patients showed clinical improvement where the shortness and chest pain were reduced, clinical symptoms improved, and pulse 90x/min. The patient is discharged with a follow-up plan every one moth.

Conclusions We reported a case of massive pericardial effusion young SLE patient. Patients receive immunosuppressive and also do pericardiasynthesis.

194 RISK FACTORS FOR BACTEREMIA IN THAI PATIENTS WITH SYSTEMIC LUPUS ERYTHEMATOSUS

B Siripaitoon\*, P Intapiboon. Prince of Songkla University, Department of Internal Medicine, Songkhla, Thailand

10.1136/lupus-2017-000215.194

Background and aims Bacteremia significantly affects mortality rate in SLE. It characterises differently across diverse geographic area. This study aimed to identify risk factors for bacteremia in Thai SLE patients.

Methods A retrospective case-control study recruited SLE patients who admitted between 2004 and 2014. Cases with significant bacteremia from microbiology database were matched with SLE diagnosis. Controls were SLE patients selected from the year of the matched case’s hospital admission with a ratio of 1:4. The admissions for elective procedure or patients having prior bacteremia were excluded. Demography, clinical features, organ involvement, SLE disease activity score, and treatments in the 3 months prior to admission were reviewed.

Results Among 87 episodes of bacteremia occurred in 68 SLE patients, gram negative bacteremia was commonly found in 62 episodes (69.7%). The most common organism was non-typhoidal Salmonella sp. (22 episodes, 25.3%). Common sites
