Background Interleukin-21 (IL-21) is a pleiotropic cytokine. Both IL-21 and the IL-21 receptor (IL-21R) have been shown to be upregulated in systemic lupus erythematosus (SLE). BOS161721, a humanized monoclonal immunoglobulin (IgG1) that binds to and neutralizes IL-21. It is currently in development for the treatment of SLE. The primary objective of this trial was to assess safety and tolerability of single intravenous (i.v.) and subcutaneous (s.c.) doses of BOS161721 in healthy volunteers (HV). **Methods** A phase 1, randomized, single-center, placebo-controlled, double-blind, single-dose-escalation trial was conducted in male and female HV (n=61) aged 18–55 years. Subjects were randomized in a 3:1 ratio (BOS161721: placebo) and received either a single SC dose of BOS161721 (1#, 3, 10, 22#, 30, 60, 120, or 240 mg, #=i.v. administration) or placebo. Key safety parameters included adverse events (AEs), injection-site reactions and detection of neutralizing antibodies (nAb) against BOS161721. Pharmacokinetic (PK) and pharmacodynamic (PD) parameters included pStat3 levels and expression levels of IL-21 gene signature in blood.

Results A total of 39 treatment emergent AEs were reported in 47 subjects (83%). The most commonly reported related AE was influenza-like illness (6.4%). No dose dependency was detected for AEs. One serious AE (fatal pulmonary embolism) was reported 127 days post dosing in a subject exposed to 240 mg SC of BOS161721; it was evaluated as not related to the study drug by the investigator. No nAbs were detected. No clinically relevant changes in laboratory parameters, vital signs or ECG were observed. Dose-linearity PK was observed with SC administration and T_{max} occurred at approximately 6 days posts dose, indicating no evidence of target mediated clearance. The mean terminal elimination half-life of BOS161721 was estimated to be 80 days at the highest dose of 240 mg. Notably, a dose dependent decrease was observed for the pSTAT3 parameter indicating complete neutralization of IL-21 signaling at doses of 60 mg and greater.

Abstract 24 Figure 1 pSTAT3 figure

Conclusions BOS161721 was safe and well tolerated in HV. Dose-linear PK of BOS161721 was demonstrated in HV. Importantly, BOS161721 potently suppressed IL-21 induced signaling which demonstrates the expected biologic and potential clinical activity of BOS161721. A phase 1b study is currently ongoing in patients with SLE.

Background Adoption of treat to target approaches for Systemic Lupus Erythematosus (SLE) requires the definition of a target state validated for improved patient outcomes. The Lupus Low Disease Activity State (LLDAS) has been shown in multiple retrospective and cross-sectional studies to have face, content, construct and criterion validity and be associated with better quality of life. We report on a multinational prospective study undertaken to determine whether LLDAS attainment is associated with protection from flare and damage accrual.

Methods A prospective multinational cohort study was undertaken in 13 centres between 2013–2017. Patients with SLE were recruited, SLEDAI-2k, SELENA flare index, PGA, and medication data collected at every visit, and damage (SLICC-ACR damage index (SDI)) collected annually. Time-dependent Cox proportional hazards models were used to assess the association of LLDAS at any time point, as well as the effect of the proportion of time spent in LLDAS, with disease flare and damage accrual (increase in SDI).

Results 1735 patients were followed for (mean $\pm$ SD) 2.2 $\pm$ 0.9 years, totalling 12 717 visits. LLDAS was achieved in 54.6% of visits. Attainment of LLDAS at any timepoint was associated with reduction in subsequent flare (HR 0.65, 95% CI 0.56–0.76, $p < 0.001$) and damage accrual (HR 0.55, 95% CI 0.43–0.70, $p < 0.001$). Similarly, patients who spent 50% of their observed time in LLDAS had reduction in risk of flare (RR 0.41, $p < 0.001$) and damage accrual (RR 0.59, $p < 0.001$), compared to those with $< 50\%$ of observed time in LLDAS. Increased durations of sustained LLDAS were associated with incremental reduction in risk of damage accrual. The protective association of LLDAS with reduced damage accrual was maintained in subgroup analysis of patients with active disease at baseline (SLEDAI-2K > 6) or pre-existing damage (SDI > 0).

Conclusions LLDAS attainment provides significant protection against disease flare and damage accrual thereby supporting its use as a treatment target in SLE, and as an outcome measure for clinical trials and treat-to-target strategies.
