Methods The Medical Outcomes Study Short Form (SF-36) and the Lupus Quality of life (LupusQol) were applied in a cohort of 38 SLE patients. At the time of HRQOL testing, all patients underwent a clinical and laboratory evaluation, together with the measure of disease activity using the Systemic Lupus Erythematosus Disease Activity Index (SLEDAI-2K). In addition, a battery of psychological tests including the Hamilton Anxiety Scale (HAS) and the Hamilton Depression Rating Scale (HAM-D) was applied.

Results The parameters which seemed to greatly influence the impairment of HRQOL were female gender, marital statuses, a higher SLEDAI-2k scores as well as higher HAS and HAM-D scores. Arthralgia-arthritis, cutaneous disease activity, neurological disease activity and renal disease activity were correlated negatively with LupusQol subscales. There was a strong positive correlation between comparable domains of instruments. Although not as strong as comparable domains, significant correlations were also found between noncomparable domains of LupusQol and PCS and MCS of SF-36.

Conclusions SF-36 and LupusQol were both beneficial instruments in evaluating HRQOL of Tunisian patients with SLE. Anxiety, depression and disease activity in some organs seem to be the major determinants of HRQOL impairment in SLE patients.

54 BLOOD CONCENTRATIONS OF COMPLEMENT SPLIT PRODUCT IC3B AND SERUM C3 ASSOCIATE WITH SYSTEMIC LUPUS ERYTHEMATOSUS DISEASE ACTIVITY

Alfred H Kim*, 2Vibeke Strand, 1Deepali P Sen, 3Qiang J Fu, 4Martin J Schmidt, 1John P Atkinson, 1Washington University School of Medicine, 2Stanford University School of Medicine, 3Saint Louis University College for Public Health and Social Justice, 4Kypha, Inc

Background A major unmet need in SLE is the identification of a biomarker that consistently tracks with disease activity. One current approach is measuring complement activation by evaluating consumption of serum C3 and C4. However, since they are acute phase reactants, interpretation of these levels is challenging as serum levels may not decrease until late in a disease flare. iC3b is a proteolytically derived molecule of C3b and increases with complement activation. iC3b/C3 ratio measures complement consumption relative to production, which may provide for a more accurate assessment of complement activation. We hypothesize that blood iC3b and iC3b/C3 levels will provide a more specific and reliable marker of complement activation and disease activity in SLE.

Methods 159 consecutive subjects with American College of Rheumatology or Systemic Lupus International Collaborating Clinics classified SLE were enrolled into CASTLE (Complement Activation Signatures in Systemic Lupus Erythematosus), a prospective observational study. Patients with 1–7 study visits were included in this longitudinal analysis. 48 healthy volunteers were enrolled to establish the normal reference iC3b/C3 ratio. Serum C3 and C4 were measured by nephelometry and blood iC3b levels by a lateral flow assay. SLE disease activity was monitored utilizing the Systemic Lupus Erythematosus Disease Activity Index 2K Responder Index-50 instrument.

Results iC3b/C3 ratio, double-stranded (ds)DNA antibodies (Abs), and supraphysiologic prednisone dose (>7.5 mg/day) each independently correlated with SLE disease activity, employing multilevel multiple logistic regression analysis. Only the iC3b/C3 ratio was significantly associated with clinically meaningful improvements in disease activity among subjects receiving supraphysiologic doses of prednisone. iC3b/C3 outperformed C3 and C4 levels discriminating both active versus inactive SLE disease and major flares versus no disease activity. iC3/C3, dsDNA Abs, ESR, and supraphysiologic prednisone dose were independently associated with lupus nephritis, while none were associated with SLE rash. The association of iC3b/C3 with nephritis was independent of other observed clinical manifestations. Finally, we observed a stronger association of the iC3b/C3 ratio with SLE disease activity in African-Americans compared to Whites.

Conclusions Blood iC3b/C3 correlates with SLE disease activity and clinically meaningful changes. Furthermore, it discriminates between active versus inactive SLE, and major flares compared to those patients without active disease. Differences in the strength of association was observed between races and manifestations.
